

1     **ABSTRACT**

2             A method identifies components associated with a first end point in an  
3     environment, such as a social environment. The method further identifies  
4     components associated with a second end point in the environment. A  
5     determination is made regarding whether any of the identified components are  
6     associated with both the first end point and the second end point. The method then  
7     displays relationships between the first end point, the second end point, and any  
8     components associated with both the first end point and the second end point.
